Part IV: Reading (Items 36 – 50)

Directions: Choose the best answer

The term biological clock is applied to the means by which living things adjust their activity patterns, without any obvious cue, to the time of day, or the year. The biological clocks seem to be beautifully adapted to the needs of living things. They are affected but little, if at all, by drugs, chemicals, or wide temperature differences - - factors which may alter substantially the rates of all ordinary processes of the body.

The nature of the biological clocks' mechanism is still mystery. Two quite different theories have been advanced to account for them. According to the first of these theories, each individual contains its own independent timing system. This is believed to have evolved, aided by natural selection, as an adaptation to the rhythmic environment. It has now become independent of the environment. According to this view, the clocks are not perfect timers. They require regular corrections by the natural light and tide cycles and the changing lengths of the day throughout the year.

The other theory holds that living things react continuously to their rhythmic physical environment. The setting of their biological clocks, therefore, involves a constant adjustment to subtle environmental forces. If this view is correct, the basic living clocks are potentially perfect timers.

Biological clocks appear to be everywhere in living things - - even in individual cells or parts of cells. But the search for the specific timing system has been futile thus far. Despite the careful study of many rhythmic phenomena and even of detailed chemical variations between cells, there is no evidence that any one of them is the clock – timer itself. Not only has no independent timing system ever been discovered, but there has not yet been even a plausible guess as to its nature.

In much the same way as it is used to detect structural flaws, ultrasound can be used to detect flaws in living tissue. The reflective properties of normal and abnormal tissues differ enough to allow them to be distinguished ultrasonically. An ultrasonic scanner can detect certain malignancies in their early stages. This diagnostic tool has been used to discover malignancies in the breast, liver, brain, and several other organs. Ultrasonic scans of a pregnant woman will show the fetus in the uterus. To minimize the risk to healthy issue, low-intensity ultrasound is used in these types of diagnoses.

In some kinds of surgery, high-intensity ultrasound can take the place of scalpels. Ultrasonic surgery is especially promising in the fields of neurology and otology. There has been some success in the treatment of Meniere's disease, an ear disorder.

The use of ultrasound may have applications in agriculture. Seeds and seedings irradiated with low-intensity ultrasound germinate faster than untreated seedings and seeds. In one case, it was reported that potato plants so treated blossomed a week ahead of time and **yielded** 50 percent more than untreated plants.

However, ultrasound can have a harmful effect on living systems. It has been pointed out that small animals exposed to high-intensity ultrasound will often die. People working with ultrasonic equipment over long periods of time suffer fatigue and nausea and sometimes disorientation.

Plants, too, while responding well to low-intensity ultrasound, can be destroyed by higher intensities. Besides cellular damage, ultrasound can also harm genetic material in the cell.

The study of ultrasonics is an expanding field. Knowledge of the **hazards** of this powerful toll will be important in developing guidelines for future research as well as for industry and biological use.

Most people throughout the world experience some form of silence. However, people's attitude toward silence is dramatically different in different cultural groups. Northern European and North American societies, for example, view silence as dark, negative, and full of 'nothing'…all of which are considered socially undesirable. In other cultures, such as Japan, however, silence is often positively valued. Here, breaking silence is a necessary evil; speaking is a negative act.

According to Wayne's study, the U.S. interpretations of silence are sorrow, criticism, obligation, regret, and embarrassment. Australian interpretations proved to be similar to the U.S. ones. However, the Japanese attitude toward silence is **favorable.** Ishikawa's survey on businessmen and businesswomen in Tokyo revealed that men need to be silent to be successful in life and that 65 percent of businesswomen would choose a silent man to marry.

Not only in business, but in every aspect of social life, people in the United States like to ask questions and force others to talk to fill interpersonal silences. So, in U.S. society and in many European societies, one function if speech is to avoid silence. Contrary to the U.S. practice, in Japanese society, silence is generally considered to be meaningful.
